EVIDENCE OF WOOD-DWELLING TERMITES IN ARCHAEOLOGICAL SITES IN THE SOUTHWESTERN UNITED STATES

KAREN R. ADAMS

Department of Ecology and Evolutionary Biology
University of Arizona
Tucson, AZ 85721

ABSTRACT.—Distinctively shaped fecal pellets of wood-dwelling termites have been recovered from a number of Southwestern archaeological contexts ranging from 600-2000 years of age. Pellet presence in a site may derive from prehistoric use of termite-infested firewood, or may signal actual termite colonization in the roofs and walls of ancient dwellings. Recovery of abundant uncarbonized pellets throughout strata should alert the archaeologist to possible post-occupational site disturbance; these same uncarbonized pellets may be useful in tracing the prehistoric geographic distributions of various Southwestern termite species. Carbonized pellets shrink differentially, depending on conditions under which they burned, and cannot be used to infer termite species identification and distribution.

INTRODUCTION

Some primal termite knocked on wood
And tasted it, and found it good,
And that is why your Cousin May
Fell through the parlor floor today.

Ogden Nash (1942)

When Ogden Nash wrote about termites with tongue in cheek, he acknowledged an insect whose history and habits have undoubtedly long interfaced with those of man. There is now evidence that wood-dwelling termites have lived close to humans in the American Southwest for at least ten centuries. Termite presence in prehistory may be signaled by distinctive fecal pellets recovered from ancient soil samples.

The archaeological record commonly reveals organic items that defy careful attempts at identification; often an ethnobiologist must be content with providing a thorough morphological description to share with colleagues. Escalated attempts at identification are justified if an unknown type occurs repeatedly in deposits at a single site, or in several locations that vary in both space and time. In the Southwestern United States a decade passed between recognition of a small item originally labeled the “Tule Springs Unknown” (Bohrer 1972:22), and its identification by an entomologist as a wood-dwelling termite fecal pellet. The connecting link was provided by a sharp-eyed graduate student who realized that small items associated with termite nests in California and Utah looked just like unidentified specimens he had observed while sorting plant and insect parts from archaeological soil samples. Subsequent comparison by the author of ancient charred “Tule Springs Unknown” specimens from a number of archaeological deposits with modern wood-dwelling termite fecal pellets confirmed the identity of the ancient unknown.

THE NATURAL HISTORY OF WOOD-DWELLING TERMITES

In contrast to earth-dwelling termites that actually inhabit soil, wood-dwelling termites are entirely confined to wood, the whole colony generally living within a small section of trunk or branch (Light 1946a). These termites enter wood directly from the air during swarming, and remain there throughout the life of the colony. Wood-dwelling termites comprise two major types: the dry-wood insects that attack only sound, dead wood with a relatively low moisture content, and damp-wood termites that require
moister, often decaying wood. Dry-wood termites can easily invade and live in wood located high above ground such as the wooden rafters of an adobe dwelling; they require no contact with the ground throughout colony life. In contrast, damp-wood termites may often be encountered in buried wood along water-courses or in buried stumps.

Distribution.—About forty species of termites inhabit the continental United States. Nearly all species are native, having been here for millenia before humans arrived on the continent. People, however, modify termite distribution by providing for their spread into new and unoccupied areas (Kofoid 1946a:7). Activities such as the transport of infested soil, wood, household furniture, and living plants provide a means by which termite colonies become established in regions wholly new for some species. Lines of fence posts and poles connecting cities and villages facilitate the spread of termites from one locality to another. Termites now inhabit colder northern regions, warmed by the same fossil-fuel burning furnaces that keep people warm.

Two families comprising five genera of wood-dwelling termites are known from native habitats in the Southwestern United States today (Table 1). They include species of both restricted and extensive distribution. Over half of the nine species occur below 1130m. Patterns of plant use vary widely among the termites, with some occurring in few plants, while others are found in a variety of plants in a broad range of habitats.

Food.—The food of termites is cellulose, one of the more resistant and durable products of photosynthesis. Cellulose is extremely abundant in the xylem, or conducting tissue, of woody plants. In general, sapwood is more appealing to a termite because it contains less lignin and a greater amount of useful organic compounds than heartwood; likewise, un-seasoned wood is more vulnerable to termite attack, as is wood felled in the summer (Kofoid 1946b:571). While termites exhibit preferences when offered a variety of wood types (Williams 1946:572) they will often eat whatever is available; even redwood, cedar and cypress, often touted as “termite resistant”, are vulnerable. Five of the termites listed in Table 1 are known to live in six or more native plants. Others opportunistically inhabit whatever tree products humans make available to them. These records suggest that choice of host material may sometimes be as much controlled by proximity as any other factor. If adequate moisture and minimum temperature requirements are met, wood-dwelling termites might be able to survive in at least some of the woody plant species in any given region.

Most termites can break down the cellulose of their plant hosts because of a symbiotic relationship with various Protozoa and bacteria that live in their gut (Kofoid 1946a:5; LaFage and Nutting 1977). Undigested residue containing from 40-60% lignin, less than 30% carbohydrates, and negligible nitrogen is eliminated (LaFage 1976:98; Lee and Wood 1971:393). Because of the relatively low moisture content of the wood they eat, wood-dwelling termites often produce compact recognizable fecal pellets (Light 1946b:215).

Fecal Pellets.—A typical pellet of a wood-dwelling termite is a small, hard, oblong object possessing six surfaces. At the angles between the six surfaces, longitudinal ridges are often visible (Fig. 1). One end of the pellet is usually blunt, while the other may appear slightly tapered or rounded reminding one of a bullet (Fig. 2). The sides of the pellet are generally parallel to one another, but may slope to one end as in pellets of Paraneotermes. The sides may be flattened, slightly convex or sometimes concave. Pellet color is quite variable, apparently related to the kind of wood being eaten (Castle 1946:281). The author has seen white, tan, brown, black and mottled modern pellets. Pellet surface texture appears finely granular at 60x magnification; when cut in cross section, the interior is of a solid homogeneous texture similar to the exterior.

Length and width of modern termite pellets vary with species. Fifty randomly chosen, entire pellets of eight Southwestern wood-dwelling species were measured under

1 Synonyms are Incisitermes texanus (Banks) and I. lighti (Snyder).
2 Synonym is Incisitermes arizonensis.
3 Represents a monotypic genus in North America.
WOOD-DWELLING TERMITE FECAL PELLETS HAVE BEEN CLEARLY DOCUMENTED IN A NUMBER OF ARCHAEOLOGICAL CONTEXTS IN ASSOCIATION WITH HUMANS IN THE SOUTHWESTERN UNITED STATES (TABLE 3). THESE PELLETS SPAN BROAD GEOGRAPHICAL AND ELEVATIONAL RANGES, AND DERIVE FROM A VARIETY OF ANCIENT SOUTHWESTERN CULTURAL TRADITIONS. ALL PELLETS ARE FROM CONTEXTS AT LEAST 600 YEARS OLD, UP TO PERHAPS 2000 OR MORE YEARS OF AGE.

MOST OF THE PREHISTORIC SPECIMENS APPEARED CHARRED TO INVESTIGATORS (FIG. 3); THESE ANCIENT ORGANIC ITEMS PROBABLY PRESERVED THROUGH TIME BECAUSE EXPOSURE TO FIRE REND ERED THEM UNAPPEALING TO DEGRADATIVE ORGANISMS. AT EACH ANCIENT SITE, SUCH CRITERIA AS CONTEXT OF RECOVERY, CARBONIZED CONDITION, AND PRESENCE OF PROTECTIVE NON-CULTURAL SEDIMENT OVER CULTURAL DEBRIS WERE EMPLOYED TO HELP RULE OUT THE POSSIBILITY THAT THESE PELLETS MIGHT BE UNRELATED TO THE PERIOD OF SITE OCCUPATION. A FEW TAN SPECIMENS, AP PARENTLY NOT CARBONIZED, WERE ALSO JUDGED TO RELATE TO SITE OCCUPATION BY THE CRITERIA OF SITE CONTEXT AND LOCATION BENEATH PROTECTIVE NON-CULTURAL OVERBURDEN. PRESERVATION OF NON-CARBONIZED FECAL PELLETS MAY BE DUE TO BOTH PELLET CONTENT AND ENVIRONMENT OF DEPOSITION. ITEMS WITH A HIGH PROPORTION OF LIGNIN ARE NOT A FOOD RESOURCE FOR MOST ORGANISMS, ALTHOUGH SOME BASIDIOMYCETES CAN THRIVE ON LIGNIN (LEO AND BARGHOORN 1976:4). BECAUSE THESE FUNGI FUNCTION OPTIMALLY ONLY IN MOIST, AEROBIC SETTINGS, TERMITE FECAL PELLETS BURIED IN DRY, OXYGEN-RESTRICTED SEDIMENTS, MAY HAVE BEEN UNABLE TO SUPPORT DECOMPOSERS.

FIG. 3.—Longitudinal view of prehistoric charred termite fecal pellets from a site along the Gila River near Florence, Arizona. Although the pellets are magnified 17x their average length of .87 mm, they probably shrank when burned. Sometimes ancient pellets occur fused to one another.

CULTURAL SIGNIFICANCE OF TERMITE FECAL PELLETS IN ARCHAEOLOGICAL SITES

Two possible routes of introduction of termite fecal pellets into ancient dwellings include transport in locally gathered firewood, and infestation of roof or side-wall construction material.

*Firewood.*—Shrubs and trees brought in for firehearth fuel may have provided one very likely avenue for termite debris to enter a dwelling. Both living and dead termite colonies...

1 All pellets measured by the author.
would be expected to harbor some pellets in the colony chambers and passageways; burning might slowly heat these protected pellets as the fire etched into the fuel source. Eventual carbonization of the pellets might result. The irregular occurrence of charred termite pellets in samples from a site in Phoenix, Arizona (Gasser 1981:359) could reflect the occasional use of termite-infested wood for hearth fuel. Charred pellets in seven separate fire-pit samples at a site near Snowflake, Arizona (Bohrer 1972), may also owe their presence to this mode of introduction.

Infestation of Wooden Roof Beams and Wall Supports.—Perhaps ancient dwellers in the Southwest experienced termite damage to various parts of their homes or towns. Puebloans of the Anasazi Tradition, as evidenced at Salmon Ruin in northwestern New Mexico, built stone and adobe towns that had multi-layered roofs of plant materials. For example, one room had a roof that consisted of a basal layer of large wooden beams (vigas) of Pinus, Juniperus and Pseudotsuga (douglas fir), topped by smaller trunks (latillas), a layer of Salix (willow) twigs, and finally Juniperus bark, all interspersed with mud and dried plant parts (Adams 1980c). Such a roof, many meters above ground level and supported by sturdy walls of adobe and stone, was vulnerable to attack by termites. Airborne infestation by wood-dwelling termites could be signaled by hexagonal fecal pellets that might drop to floors below and be recovered in soil samples taken centuries later. While Dr. William Robinson of the Laboratory of Tree-Ring Research in Tucson, Arizona has not observed termite damage in any of the large prehistoric beams taken from structures in the Chaco, Mesa Verde or Kayenta Cliff Dwelling areas (Letter Jan. 8, 1982), perhaps the smaller latilla or twig layers provided suitable nesting sites. Finding termite-galleried wood in ancient roof debris is needed to confirm this hypothesis.

Prehistoric dwellers of the Hohokam Tradition in Arizona built structures unlike the communal pueblos of the Anasazi. Single houses, often partially sunken into the ground, were common among the Hohokam. The side walls of dwellings constructed at Snake-town, a large Hohokam town in central Arizona, were fashioned of such plants as Populus (cottonwood) and Prosopis (mesquite), and occasionally of Juniperus. Mesquite and cottonwood were also used for the overhead rafters and lighter layers that comprised the roof (Sayles 1958:81; Haury 1978:72). One can speculate that these plant materials may have housed termites.

ENTOMOLOGICAL/ENVIRONMENTAL SIGNIFICANCE

The broad geographic and elevational distribution of termite fecal pellets in the archaeological record posed the intriguing possibility of discerning the prehistoric distribution pattern of termites. Entomologists might appreciate a prehistoric biogeographical view of termite range, while archaeologists might have yet another means to infer local site conditions by knowing what termites lived nearby. Length and width measurements of modern pellets were secured to determine if one or perhaps a few of the species could be distinguished from all others. The resulting dichotomous key based on modern termite pellet population statistics (Fig. 4) revealed that, as with any naturally varying group of organisms, some species had unique attributes while others had pellets with characteristics shared in common by one or more species.

The real problem with identifying ancient termites from their pellet morphology does not lie with overlapping population characteristics however. Carbonization experiments performed on carefully measured populations of modern pellets revealed that shrinkage in both length and width dimensions can be moderate to severe (Table 4), depending upon amount of oxygen present and length of time exposed to fire. The variable nature of termite pellet shrinkage parallels that found by researchers undertaking modern seed carbonization experiments. Seed size changes due to burning vary with inherent seed differences (Renfrew 1973:11-13), moisture content (Stewart and Robert-

son 1971:381), as well as maturity, evenness of carbonization and total amount of charring (Brugge 1965:49). It would be impossible to know, in this case, how much shrinkage had been experienced by pellets recovered from the ashes of an ancient firepit. Since the bulk of pellets recovered from Southwestern archaeological sites to date have been carbonized\(^1\), at present the size dimensions give no clues to the identity of the termites. As uncarbonized pellets are recovered, however, they should be classified in the hopes that both environmental information and the distribution of prehistoric termites may become known.

TERMITES AS AGENTS IN THE DISTURBANCE OF ARCHAEOLOGICAL SITES

In addition to suggesting prehistoric termite biogeography, abundant uncarbonized pellets in an ancient site might serve as a clue to pre or post-depositional modification of strata. For example, wood-dwelling termites could easily inhabit dense organic deposits that are typical of dry caves or rock overhangs in the American Southwest. As termites utilized buried wood, sediment mixing could occur as internal, now-empty spaces collapsed downward. The archaeologist should consider such a natural transformation process in deposits that reveal broad distribution and fair numbers of uncarbonized pellets.

Earth-dwelling termites could also play a major role in soil mixing of non-cave archaeological sites, where moisture content is generally higher. Termites in North America have been known to mix, alter, invert and obliterate soil horizons, as well as create new horizons and affect the spatial boundaries of different soils (Wood and Johnson 1978:325). Not only might termites mix soils, but they could also provide channels for air and water to move downward through deposits and thus increase chances of oxidation of organic material and destruction by fungi and bacterial degradative organisms. Since earth-dwelling termites do not produce recognizable six-sided fecal pellets, spotting their former presence in a site would be difficult.

SUMMARY

Fecal pellets from wood-dwelling termites had been isolated from Southwestern United States archaeological soil samples for at least ten years before their identification was secured. Potential avenues for the introduction of termite fecal pellets into ancient
dwellings include plant materials carried in as fuel, and infestation of roof or wall supports. Often the pellets are charred in ancient deposits. Carbonization experiments performed on modern pellets in the presence and absence of oxygen reveal that termite pellets shrink from 6-30% in both length and diameter. Therefore, the possibility of inferring ancient termite distribution from the morphology of carbonized pellets from archaeological sites seems remote. While this particular record is mute regarding biogeographical and ecological data, other non-burned records may not be so. In a dry site, such as a cave or rock overhang, widespread occurrence of non-burned pellets could signal extensive termite colonization and potential mixing of site deposits. The identification and interpretation of insect remains from archaeological sites remains a largely unexplored, and undoubtedly rich, source of information.

ACKNOWLEDGMENTS

The keen sense of observation of Mr. Alan C. Reed, while a graduate student at Eastern New Mexico University, provided the first clue that an unknown item from a number of Southwestern archaeological sites might derive from termites. Without reservation Dr. William L. Nutting of the Department of Entomology, University of Arizona, confirmed the hunch. Dr. Nutting also provided guidance and, along with Dr. Michael K. Rust of the University of California, Riverside, supplied me with modern termite fecal pellets for examination. Vorsila L. Bohrer not only recovered and described the first “Tule Springs Unknown” specimens, she also served as the catalyst for this study. My parents Louise and Adrian Rogers assisted with technical details, and Cynthia Lindquist photographed the modern and ancient pellets. Colleagues in ethnobiology, noted in Table 3, kindly sent me ancient termite pellet specimens for scrutiny.

NOTE

To distinguish naturally black items from those turned black by exposure to heat, one can gently scratch the specimen against a piece of white paper, and a carbonized item will generally leave a slight streak or smudge.

Book Review

From an overture punctuated by spadefoot toads and desert thunderstorms, to a pastorale of bird-song around a desert oasis, and a crescendo of mariachi and Papago polka bands, The Desert Smells Like Rain presents an intimate view of the Sonoran Desert and its native people. Ethnobiologist Gary Nabhan shares his experiences and insights while studying run-off agriculture and traditional crops in the borderlands of Arizona and Sonora. These adventures include a trek to I'itoi's cave in the Baboquivari Mountains, a visit to a saguaro wine-drinking and rain-bringing ceremony, expeditions to two relic oases in the desert, and a pilgrimage to the Fiesta of San Francisco Xavier in Magdalena, Sonora. Along the way he introduces the reader to his Papago acquaintances, who are more friends than just informants.

In other chapters, Gary Nabhan explores the relationship between the disappearance of traditional foods and dietary patterns and the endemic increase of diabetes, cardiovascular problems, and other nutrition-related diseases among the Papago. He also examines the native view of the indigenous wild relatives of important cultivated plants. Wild tepary beans, gourds, cotton, and tobacco are all considered to be plants that Coyote, the trickster deity, has stolen or otherwise spoiled. An important theme throughout The Desert Smells Like Rain is Papago cognition of the changing hydraulic regime of the Sonoran Desert and the abandonment of traditional floodwater farming.

Ethnography, germplasm conservation, linguistics, and traditional agriculture are interwoven with insight, myth, and humor in The Desert Smells Like Rain. An extensive collection of notes and references is included, but in the back of the book where it doesn't interrupt the flow of the text.

Gary Paul Nabhan should be added to the list of authors that includes Alfred Russel Wallace, Charles Darwin, Edgar Anderson, and Stephen Jay Gould, natural history writers with the unique talent of being able to present a tremendous amount of information in an enjoyable and very readable style.
